

Toyota is implementing research and development work on plug-in hybrid vehicles (PHV). A PHV is chargeable from a household electric outlet. For city driving, it can be used as an electric car. For long trips, it can function like a hybrid. The PHV is another vehicle designed to advance the concept of 'Sustainable Mobility'.

As a responsible corporate citizen, we're consistently advancing such green initiatives to the next level. In order to achieve sustainable mobility – an automotive society that co-exists with nature.

Personal Mobility

As part of progressing the concept of Personal Mobility, Toyota aims to create cars that are in unison with a person's senses.

This technological insight came alive with the release of the i-Unit. Designed as an anti-collision car using communication functions, the i-Unit pushes the boundary by allowing the driver to control his mobility at will. Another Toyota initiative towards increasing the fun and excitement of driving.

Next came the i-Swing, a personal mobility vehicle that lets drivers express their individuality. A single-person car, the i-Swing is designed to feel closer to the body, and to fit the driver more like a dress. Using A.I. technology, the car interacts with the user in the virtual world, by storing relevant data and responding to user perceptions more effectively.

The latest in this line is the i-Real - a single-person concept car that pushes the realms of personal mobility. Engineered with careful precision, this 3-wheeled city commuter represents a more personal form of communication between car and driver. The car is designed closely in human scale, as a step towards commercialization in the near future.

Robots

Living in the digital age, Toyota recognizes the need to design technology that simplifies life. It understands that people around the globe are increasingly looking for diversified lifestyles. To address these issues, Toyota is promoting the development of human-assisting Partner Robots, using its expertise in automotive development and product engineering. These robots are designed to skillfully operate a variety of human functions, while also displaying human qualities of warmth as well as intelligence, thus bridging the gap between people and technology.

IN INDIA:

Toyota is working closely with 'The Energy and Resources Institute of India' to solve issues that come standard with economic development, such as urban problems and distribution access. We are also observing simulations for tackling air pollution, as well as working on developing an eco-friendly car.

Sustainability through Manufacturing

Manufacturing

Toyota understands the crucial nature of sustainability, not just in its products, but also in its plants and manufacturing process. To make this process sustainable, Toyota is expanding its sustainable production plants, by creating

them in harmony with nature. This is achieved by using more natural resources in manufacturing, such as solar and wind power, and also by planting trees around the site to preserve its natural environment. Our energy and resource conservation activities make our plants sustainable for over 100 years. Our logistic system and resource-recycling plans are highly eco-focused. The Toyota Production System eliminates waste, inconsistencies and unreasonable requirements.

IN INDIA:

Since its establishment, Toyota Kirloskar Motor's Bangalore plant has been equipped with wastewater treatment facilities that help recycle 100% of the wastewater produced. Furthermore, its steel usage rate is in the top of its class among Asian Toyota factories, achieving effective usage of resources and a reduction in CO₂ emissions. There's also a rainwater harvesting pond that conserves rainwater and protects groundwater resources. The Weather Monitoring Stations help give in-depth details of dispersion of atmospheric pollutants. Tree-planting initiatives are also a regular part of TKM's activities. These practices go a long way in helping conserve resources and minimize waste.
